

# On the Fixed Points of Elliptic Elements of Finitely Generated Function Groups

Shigeyasu KAMIYA

(Received September, 16, 1978)

In the previous paper [1], we showed some properties of the fixed points of elliptic elements of  $B$ -groups.

In this paper we study the similar properties in the case of finitely generated function groups.

Before stating our theorem we shall explain notation.

Let  $E(G)$  be the set of fixed points of elliptic elements in  $A(G)$ . Let  $E_d(G)$  (resp.  $E_e(G)$ ) be the subset of  $E(G)$  consisting of the fixed points of elliptic elements in some degenerate factor subgroup (resp. some elementary factor subgroup) of  $G$ .

Our result is the following theorem.

**THEOREM.** *Let  $G$  be a finitely generated function group with an invariant component  $A_0$ . Then the following four propositions hold:*

(1)  $E(G) = E_d(G) \cup E_e(G)$ .

(2) *For any  $z \in E(G)$ , if  $z$  is fixed by an elliptic element with the period  $r \geq 3$ , then  $z$  can not lie on the boundaries of components except  $A_0$ .*

(3) *Let  $H$  be some factor subgroup of  $G$ . For  $z \in A(H)$ , if  $z$  is fixed by an elliptic element with the period  $r \geq 3$  and a parabolic element, then  $H$  is an elementary group.*

(4) *Let  $E$  be an elliptic element in  $G$  and  $a, b$  its fixed points. If any factor subgroup is not finite, both  $a$  and  $b$  can not lie in  $A_0$ .*

**1.** Let us begin with recalling some notation and definitions.

Let  $G$  be a Kleinian group,  $\Omega(G)$  the region of discontinuity, and  $A(G)$  the limit set of  $G$ . The components of  $\Omega(G)$  are called components of  $G$ . A component  $A_0$  of  $G$  is called invariant if  $V(A_0) = A_0$  for every  $V \in G$ . If  $A$  is a component of  $G$  other

than the invariant component, then the subgroup  $G_{\mathcal{A}}$  of  $G$  keeping  $\mathcal{A}$  invariant is called a component subgroup of  $G$ .

A kleinian group with an invariant component is called a function group. Throughout this paper we denote a finitely generated function group by  $G$ . A subgroup  $H$  of  $G$  is called a factor subgroup if  $H$  is a maximal subgroup of  $G$  with the following properties: the invariant component of  $H$ , which contains the invariant component of  $G$ , is simply connected;  $H$  contains no accidental parabolic transformations; if  $V \in G$  is parabolic and the fixed point of  $V$  lies in  $\Lambda(H)$ , then  $V \in H$ . If  $H$  is a factor subgroup of  $G$ , then  $G$  is elementary, degenerate, or quasifuchsian.

**2.** Now we are ready to prove our theorem.

PROOF OF (1). It is well-known that an elliptic element in  $G$  is an element of some factor subgroup of  $G$  and that the set of component subgroups equals the set of quasifuchsian factor subgroups. Using the above fact, in the same manner as in the proof of (1) in [1], we can show that  $E(G) = E_a(G) \cup E_c(G)$ .

PROOF OF (2). Take  $z$  in  $E(G)$ . Let  $E$  be an elliptic element with a fixed point  $z$  and its period  $r$ . Let  $\mathcal{A}$  be a component except  $\mathcal{A}_0$ . Assume that  $z$  lies on the boundary  $\partial\mathcal{A}$ . Since  $G_{\mathcal{A}}$  is a quasifuchsian group, the element  $E$  does not belong to  $G_{\mathcal{A}}$ . Therefore  $\mathcal{A} \neq E(\mathcal{A}) \neq E^2(\mathcal{A})$ , so  $z \in \partial\mathcal{A} \cap \partial E(\mathcal{A}) \cap \partial E^2(\mathcal{A})$ . This contradicts Theorem 5 in [3]. Hence  $z$  can not lie on the boundaries of components except  $\mathcal{A}_0$ .

PROOF OF (3). If  $z$  is fixed by an elliptic element  $E$  with the period  $r(\geq 3)$  and a parabolic element  $P_1$ , then there exists a parabolic element  $P_2$  such that  $P_2(z) = z$  and  $P_1^m \neq P_2^n$  for any non-zero integers  $m$  and  $n$  (cf. [1]). Since  $H$  is a factor subgroup of  $G$ ,  $P_1$  and  $P_2$  belong to  $H$ . Using Lemma 2 in [1], we see that  $H$  is not a  $B$ -group. Therefore  $H$  is an elementary group.

PROOF OF (4). Suppose that  $a$  and  $b$  lie in  $\mathcal{A}_0$ . It is known that  $E$  belongs to some factor subgroup  $H$  of  $G$ . If  $H$  is a quasifuchsian group, one of its invariant components, say  $\mathcal{A}$ , is a component of  $G$  and so either  $a$  or  $b$  lies in  $\mathcal{A}$ . Hence both  $a$  and  $b$  can not be contained in  $\mathcal{A}_0$ . Next we consider the case of the group  $H$  which is degenerate. In this case, either  $a$  or  $b$ , say  $a$ , lies in  $\Lambda(H)$ . (cf. [1]). Therefore  $a$  is contained in  $\Lambda(G)$ . When  $H$  is an elementary group with one limit point, we can show by the same way as the above that both  $a$  and  $b$  can not lie in  $\mathcal{A}_0$ .

Thus our theorem is completely proved.
